PREFACE

India houses seventy percent of the global population of tiger in seven percent of their historic range. These tigers are present in tiger reserves that are mostly geographically aloof from each other. They are separated by landscapes of intensive human occupation including expanding agriculture and urbanization. This problem of isolation is further aggravated by aggressive infrastructural development which is fueled by a national aspiration to 8% economic growth and without the presence of a comprehensive land-use policy. Moreover, these reserves that contain these isolated meta-populations are in themselves not enough to sustain a sizeable tiger population. Under such circumstances it is imperative that these habitats or Protected Areas be connected and corridors are the best available measure that the global conservation community unanimously vouches for. In India all tiger corridors are heavily affected by anthropogenic pressures, which is exerted by human population of 1.25 Billion people increasing at a rate of 1.7% annually. This demands the immediate attention of all respective wildlife managers. This atlas provides village level maps and data for tiger corridors of the Eastern Vidarbha Landscape that will be useful for the managers to take proactive measures in field.

INTRODUCTION

TIGER
CORRIDORS
OF EASTERN
VIDARBHA
LANDSCAPE

Protected areas (PA) were established in India to provide wild animals with a refuge in the face of habitat loss due to escalating anthropogenic pressures from an ever growing human population in the country. Some of these PAs were later designated as tiger reserves (TR), under Project Tiger Scheme in 1973, with the intension of providing further protection to all the wild species present, under the umbrella of the Bengal Tiger (*Panthera tigris tigris*). The presence of viable populations of tigers is an indicator of the integrity, sustainability, and health of larger ecosystems. Tiger landscapes support tigers, co-predators, their prey, and a vast amount of biodiversity. They also contribute to human wellbeing, locally and globally, through the provision of many ecosystem services such as water harvesting, carbon sequestration, plant genetic materials, food security, medicinal plants, and opportunities for community-based tourism.

Most PAs and TRs appear as islands of forest in a sea of human dominated landscapes. In such a scenario, habitat connectivity is extremely essential to prevent species extinction by isolation of population and or restriction of gene flow. Loss of habitat connectivity in close proximity to a tiger source area, owing to Landuse Landover change due to various reasons, leads to straying of tigers near human dominated areas in the landscape (NTCA 2013). Besides, tigers dispersing from one landscape (source) to another (sink) traverse modified landscapes using agricultural fields and similar cover along river courses, feeding on livestock or native wild prey. Dispersing tigers utilize habitats with varying degree of human disturbance and varying Landuse. After leaving the natal areas, the animals get noticed either by people or by forest department in an area, which probably is not conducive for their movement (chance encounter of either sign or direct encounter with humans increase). Therefore, tiger conservation in India solely depends on identification of structural and functional dispersal corridors and on mitigation of conflicts with humans along these.

Habitat loss and fragmentation have been recognized throughout the world as a key issue facing the conservation of biological diversity (IUCN 1980). As the global population increases, less and less of Earth's surface remains free from human interference. Human activities have modified the environment to the extent that

the most common landscape patterns are mosaics of human settlements, farmland and scattered fragments of natural ecosystems. Destruction and degradation of natural habitats are widespread and profound and their implications for the conservation of biological diversity and the sustainability of natural resources are of global significance (Bennett 1999). Closely coupled with the issue of broad-scale loss of natural habitats is the challenge of maintaining and conserving biodiversity in landscapes now dominated by human land use. In many such landscapes, large natural tracts are becoming scarce or no longer exist. Remnants of the natural environment increasingly occur as a mosaic of large and small patches, survivors of environments that have been carved up to develop new forms of productive land use for humans. Together they provide the habitats upon which the conservation of much of the flora and fauna in developed landscapes ultimately depends.

Under such scenario, the connectivity of such isolated fragments becomes important. This can be achieved by linking these fragments by a corridor of similar suitable habitat, which will impart a greater conservation to this new arrangement (Diamond 1975; Wilson and Willis 1975). This initial recommendation was based entirely on theoretical considerations, primarily stemming from island biogeographic theory. Subsequently, protection or provision of continuous corridors of habitat to link isolates such as nature reserves, woodlands or patches of old-growth forest have been widely recommended as conservation measures to counter the impacts of habitat reduction and fragmentation. Besides, the concept of corridors as a conservation measure has been highly successful in catching the attention of planners, land managers and the community.

In the face of habitat fragmentation, persistence of wildlife populations depends, at least in part, on their ability to move through modified landscapes. Such movements allow individuals to forage over multiple habitat patches, rescue local populations from extinction, or recolonize local populations after extinction. The interaction between animal movements (set by physiology and behaviour) and landscape structure (set by landscape composition and configuration) will determine the ability of an animal to move through a landscape. (Merriam 1984) referred to the landscape property resulting from this interaction as "connectivity". Landscape

connectivity was later defined as "the degree to which the landscape facilitates or impedes movement among resource patches" (Taylor et al. 1993) and is both species-specific and landscape-specific (Tischendorf and Fahrig 2000a). Understanding the impact of landscape change on landscape connectivity is essential for predicting the impact of landscape change on a species (Goodwin and Fahrig 2002).

A wildlife corridor is an area of habitat connecting wildlife populations separated by human activities (such as roads, development, or logging). This allows an exchange of individuals between populations, which may help prevent the negative effects of inbreeding and reduced genetic diversity (via genetic drift) that often occur within isolated populations. Corridors may also help facilitate the re-establishment of populations that have been reduced or eliminated due to random events (such as fires or disease). This may potentially moderate some of the worst effects of habitat fragmentation (Goodwin & Fahrig 2002). The negative response of landscape connectivity to large inter-patch distance suggests that measures like decreasing isolation, through corridors (Merriam 1991; Noss 1993; Rosenberg et al. 1998), have the potential to increase landscape connectivity.

Connectivity depends on the characteristics of the habitat patches and the distance between patches (Ewers and Didham 2006) but also on the suitability and permeability of the matrix (Powney et al. 2011; Vergara 2011). Landscape connectivity is also dependent on some landscape characteristics, which modify interspecific relationships (Ewers and Didham 2006; Wakano et al. 2011) and mortality risks (Tischendorf & Fahrig 2000b). Thus, species success or failure depends on features of landscape patches and landscape characteristics that need to be taken into account when estimating connectivity (Kadoya 2009; Sawyer et al. 2011). Using movement data to estimate connectivity within a species' territory requires very important logistical and economical resources (Zeller et al. 2012), which become even more important when multi-species connectivity is considered. Goodwin & Fahrig (2002) showed that landscape structure was strongly correlated to connectivity, especially habitat area and inter-patch distance.

There is very little information about which animal species actually use vegetation corridors during dispersal (Arnold et al. 1991; Bentley and Catterall 1997; Cale 1990; Desrochers and Hannon 1997; Hinsley et al. 1995; Saunders and De Rebeira 1991), or about how effective differently connected landscapes may be for species with a range of different dispersal behaviors. For example, a landscape with corridor gaps (discontinuities) of 100 m may be fine for a large parrot that needs only visual

contact to move from patch to patch (Saunders and De Rebeira 1991), but useless for a small arboreal lizard if that lizard never moves far from the safety of trees (Sarre et al. 1996).

Earlier, most tiger ecological research efforts have focused on investigating behavioral aspects such as communication, territoriality, land tenure, dispersal and social organization within a few protected areas (Karanth and Sunquist 2000; Seidensticker 1976; Smith 1993; Sunquist 1981). These basic studies of tiger behaviour formed the foundation of more advanced population level studies. Although ecological studies of large carnivores within a modern scientific framework began forty years ago with George Schaller's pioneering work in Kanha National Park (Schaller 2009) and have advanced tremendously thereafter as a result of research by other scientists (Karanth et al. 2003). Major scientific advances in understanding tiger ecology were made in the 1973-1985 period through radio telemetry studies in Chitwan, Nepal under the Smithsonian Tiger Ecology Project (Seidensticker 1976; Seidensticker and McDougal 1993; Smith et al. 1987; Smith 1993; Sunquist and Sunquist 2002). During the 1990s, long-term ecological studies in Nagarhole (Karanth and Stith 1999; Karanth and Sunquist 1992, 1995, 2000), Panna (Chundawat et al. 1999) and other areas of India and Nepal (Biswas and Sankar 2002; Karanth and Nichols 1998; Karanth et al. 2004; Karanth et al. 2000; Karanth et al. 2003; Wegge et al. 2004) that employed modern techniques such as radio-telemetry, camera trapping, dietary analyses and prey density estimation, generated substantial new knowledge about wild tigers. Recent initiatives by NTCA, State Forest Departments along with Wildlife Institute of India for long term monitoring of Tigers in Kanha Tiger Reserve, Pench Tiger Reserve, Sundarbans, Panna Tiger Reserve, Ranthambore Tiger Reserve and Bhandavgarh Tiger Reserve will produce enough information vital for long term conservation of wild tigers and co-predators in India. Landmark population estimation exercise at national level by NTCA and Wildlife Institute of India (Jhala et al. 2015, Jhala 2011; Jhala et al. 2008) identified the critical tiger populations for long term monitoring in India.

It is evident from the above studies that without habitat connectivity between the TRs, tigers are doomed to extinction in the long run, in spite of conservation measures adopted within TRs. Further, studies on tiger corridors stress the importance of habitat connectivity and the pressures that existing tiger corridors face in India (Joshi et al. 2013, Sharma et al. 2013a, Sharma et al. 2013b, Yumnam et al., 2014). Qureshi et al. (2015) published an atlas of tiger corridors at country scale, which has its own limitations of finer details that can be rendered.

In this atlas we present tiger corridor maps of the Eastern Vidarbha landscape using fine scale models, simultaneously providing all data at village level that will be useful for wildlife managers.

STUDY AREA

The Eastern Vidarbha Landscape (EVL) or the Nagpur Division is one of six administrative divisions of Maharashtra State in India. Nagpur is the easternmost division in the state, with an administrative headquarters in the city of Nagpur. It lies between 18° 11' 20.69" N to 21° 43' 15.79" N and 78° 03' 37.09" E to 80° 54' 09.42" E. It encompasses an area of 51,000 km² covering the six districts of Bhandara, Chandrapur, Gadchiroli, Gondia, Nagpur, Wardha. It houses a human population of 1,17,54,434 people, and at the same time has a forest cover of about 20,000 km². This patch of forest is very important as it harbours a population of about 150 tigers and forms the connecting link between the central and southern Indian tiger populations (Jhala et al. 2015). It plays a pivotal role in exchange of individuals and thereby facilitates gene flow between these two populations increasing the viability of tiger populations in India. There are 8 protected areas or wildlife divisions where these tigers live, but these refugia are scattered like islands in a sea of human dominated landscape. So knowing the locations of tiger movement corridors and probable areas of human tiger conflict is very important for a wildlife managers. This atlas provides detailed maps of corridors in the form of large scale 10 X 10 km tiles, along with information like village boundaries and land use, overlaid on them. We have also provided important information like number of households, total human population, proportion of people involved in agriculture and total livestock population of a village. These information, we believe, can be used to make meaningful management decisions in the field.

DATA AND METHODS

Tiger presence data

Tiger presence data was recorded during occupancy surveys and sign surveys in the corridor areas of Eastern Vidarbha Landscape. Presence locations were also obtained from locations of camera traps deployed by the forest department.

Village level data

Village boundary was obtained from Survey of India (SOI). It was overlaid on the corridors to help managers have a spatial ideas about the location of the villages with respect to the tiger corridors. We used Census of India 2011 data to provide village-wise, human population data and data on agricultural workers. We have also provided total livestock data for each villages. We believe that livestock may act a prey base for tigers in areas away from protect areas or forested areas. Besides, livestock depredation is a major source of human-tiger conflict in EVL. Livestock data was obtained from Department of Animal Husbandry, Government of Maharashtra. This data was generated as a part of the Nineteenth All India Livestock Census in 2012.

Remotely sensed variables

We used forest cover data which was obtained from the Forest Survey of India (FSI 2009) that is based on IRS 1D LISS III satellite with 4 multispectral band data at 23.5 m resolution. Landuse data at a scale of 1:250,000 was obtained from Bhuvan, the online data dissemination portal of ISRO. This data is a product of the Ninth Cycle (2012-13) National land use and land cover mapping using multi-temporal AWiFS data (LULC-AWiFS). Night light data, which was treated as a surrogate for intensity of human use, was obtained from U.S. Air Force Defense Meteorological Satellite Program (DMSP) and National Oceanic and Atmospheric Administration's (NOAA) Operational Linescan System (OLS) (<http://www.ngdc.noaa.gov/dmsp/sensors/ols.html>; accessed Dec 18, 2010). Road and drainage information were obtained from Digital Chart of the World (<http://statisk.umb.no/ikf/gis/dcw/>; accessed Dec 20, 2015). Protected Area shape files were obtained from the GIS cell of the Wildlife Institute of India. Euclidean distances to roads, drainage, Protected Areas and forested areas were computed in ArcGIS 10.2 (www.esri.com) software.

Modelling of habitat permeability

We used remotely sensed data viz., forest cover, forest type and human footprint; and Euclidean distance layers to protected areas, forest areas, roads and drainage,

along with tiger presence data to model habitat permeability. We did Jackknifing to select the appropriate set of variables from among these 3 remotely sensed variables and 4 distance matrices. Maxent ver. 3.3.1 (<http://www.cs.princeton.edu/~schapire/maxent/>; Merow 2013, Phillips et al. 2004, 2006) was used for habitat permeability modelling. Model evaluation was done using ROC curve and the model was evaluated using test data. The best performing model was used to delineate areas that may be preferred by tiger across the landscape for movement. Then we used this preference layer (conductance raster) as an input for Circuit Theory analysis to delineate corridors.

Circuit Theory and Corridor Modelling

Circuit Theory considers the landscape as an electronic circuit board and each suitable habitat patch as a node. Here the flow of electric current is analogous to the movement of a tiger. In the model, current of one ampere is passed between the nodes, following all possible pathways made up by combining different landscape circuit linkages between the source and sink nodes. This operation assigns a current value to each landscape raster cell equivalent to the amount of current flowing through it, which yields a current map depicting the distribution of current values across the landscape. Places with high current values, depicts areas, which are favored by the tiger for movement between habitat patches as compared to the low values (Figure 3). This implementation was done using the software Circuitscape 4.0 (McRae, 2006; McRae and Beier, 2007; McRae et al., 2008; Shah and McRae, 2008).

Modelling of bottlenecks/ pinch points

A combination of least cost pathway and Circuit Theory was used along with centrality analysis to identify pinch points or bottlenecks in the forested corridors. We used Pinchpoint Mapper, a toolbox for ArcGIS 10.2 to model the pinch points (McRae & Kavanagh 2011). We believe that these pinch points (Figure 4) are places where the corridor is in its most critical state, i.e. there may be fragmentation and excess human pressure because of the presence of a village. In other words, at these places the corridors are too narrow to tolerate the percolating effect of human disturbance, and they are devoid of any inviolate linear passages which the tiger may actually use for movement. So there are areas which most possibly are very prone to human tiger conflict. Maps for pinch points/ bottlenecks have been displayed after the plates for the corridors. These modelled pinch points needs to be validated on ground.

Figure 5 shows an overall map of corridors for the EVL with numbered 10 X 10 km grids overlaid on them. Grid-wise detailed maps have been provided with data. The user can select the grid that he/ she wants to look at, from the index map, and refer to the subsequent detailed map for a better view. Abbreviations have been used as field names and key to those abbreviations are provided below (Table 1). Each detail map is provided with the grid number at the upper left corner followed by coordinate locations of the center of each grid. A 3X3 reference grid depicting adjacent cell numbers has also been provided along with a legend to read the landuse/landcover map.

Table 1

Key to abbreviations used in the data tables.

Key to table headings:

Area	: Area of the village in Hectares
No_HH	: Number of Households
TOT_P	: Total Population
Main_CL_P*	: Main Workers Cultivators - Persons
Main_AL_P*	: Main Workers Agricultural Labourers - Persons
Marg_CL_P*	: Marginal Workers Cultivators - Persons
Marg_AL_P*	: Marginal Workers Agricultural Labourers - Persons
Livestock	: Total number of livestock in a village
Land_Fores	: Hectares of notified forest land in a village

* Proportion of total population.

CONFLICT POTENTIAL MAP

Human carnivore conflict arising from livestock depredation or direct attack on humans is a major challenge for conservation practitioners in India. If not addressed properly affected local communities may resort to lethal means to reduce carnivore attacks, which may lead to rapid declines in local carnivore population. The same holds true for tigers in EVL. Proving wildlife managers with a potential conflict map may help them anticipate such conflict scenarios before-hand and plan for appropriate management interventions for prevention or mitigation of human-tiger conflict.

In this study, we have tried to develop a human-tiger conflict potential map. We have assumed that when areas of intensive human activity and high tiger movement overlap, chances of conflict increases. We gridded EVL into 5 X 5 km grids and calculated mean human density and mean tiger movement potential for each grid. We then ranked the human and tiger data separately from 0 to 3. After ranking, we multiplied the human and tiger use intensity together to get the conflict potential map (Figure 6).

ACKNOWLEDGEMENT

We are thankful to National Tiger Conservation Authority (NTCA) for financial assistance to the research project titled "Evaluating landscape use by dispersing / stray Tigers and modeling potential connectivity bottlenecks". We are thankful to Maharashtra Forest Department (MFD) for necessary permissions and logistic support. We acknowledge the administrative support by NTCA and MFD. We also thank following people for their encouragement and continuous support during the project.

Sh. Praveen Pardesi, IAS

Principal Secretary to the CM
Govt. of Maharashtra
